Design of concrete grammars

Objectives

The concrete grammars for **parsing**

- is parsable - fulfills the **grammar condition** of the chosen parser generator;
- specifies the **intended language** - or a small super set of it;
- is provable related to the **documented grammar**;
- can be **mapped to** a suitable **abstract grammar**.

Lecture Compiler I WS 2001/2002 / Slide 59

Objectives:

Guiding objectives

In the lecture:

The objectives are explained.

Grammar design for an existing language

- Take the grammar of the **language specification literally**.
- Only **conservative modifications** for parsability or for mapping to abstract syntax.
- **Describe any modification**.
  (see ANSI C Specification in the Eli system description
  http://www.uni-paderborn.de/fachbereich/AG/agkastens/eli/examples/eli_cE.html)

  - **Java** language specification (1996):
    Specification grammar is not LALR(1).
    5 problems are described and how to solve them.
  - **Ada** language specification (1983):
    Specification grammar is LALR(1)
    - requirement of the language competition
  - **ANSI C, C++**:
    several ambiguities and LALR(1) conflicts, e.g.
    „**dangling else**“,
    „**typedef problem**“:
    `A (*B);`
    is a declaration of variable **B**, if **A** is a type name,
    otherwise it is a call of function **A**

Lecture Compiler I WS 2001/2002 / Slide 60

Objectives:

Avoid document modifications

In the lecture:

- Explain the conservative strategy.
- Java gives a solution for the dangling else problem.
- Explain the typedef problem.

Grammar design together with language design

Read grammars before writing a new grammar.

Apply **grammar patterns systematically** (cf. GdP-2.5, GdP-2.8)

- repetitions
- optional constructs
- precedence, associativity of operators

Syntactic structure should reflect semantic structure:

E. g. a range in the sense of scope rules should be represented by a single subtree of the derivation tree (of the abstract tree).

Violated in Pascal:

functionDeclaration ::= functionHeading block
functionHeading ::= ‘function‘ identifier formalParameters ‘:‘ resultType ‘;‘

formalParameters together with block form a range,
but identifier does not belong to it

Lecture Compiler I WS 2001/2002 / Slide 61

Objectives:

Grammar design rules

In the lecture:

- Refer to GdP slides.
- Explain semantic structure.
- Show violation of the example.

Syntactic restrictions versus semantic conditions

Express a restriction **syntactically** only if
it can be **completely covered with reasonable complexity**:

- **Restriction can not be decided syntactically**:
  e.g. type check in expressions:
  BoolExpression ::= IntExpression ‘<‘ IntExpression

- **Restriction can not always be decided syntactically**:
  e. g. disallow array type to be used as function result
  Type ::= ArrayType | NonArrayType | Identifier
  ResultType ::= NonArrayType
  If a type identifier may specify an array type,
  a semantic condition is needed, anyhow

- **Syntactic restriction is unreasonable complex**:
  e. g. distinction of compile-time expressions from ordinary expressions requires duplication of the expression syntax.

Lecture Compiler I WS 2001/2002 / Slide 62

Objectives:

How to express restrictions

In the lecture:

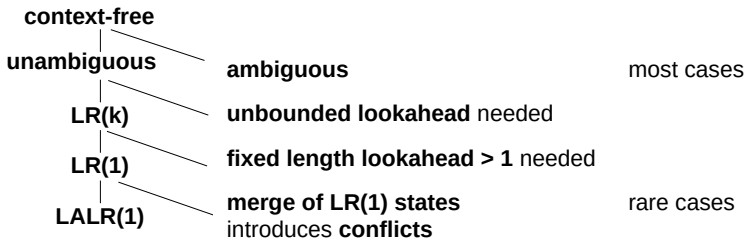
- Examples are explained.
- Semantic conditions are formulated with attribute grammar concepts, see next chapter.

Assignments:

Discuss further examples for restrictions.

Reasons of LALR(1) conflicts

Grammar condition does not hold:



LALR(1) parser generator can not distinguish these cases.

© 2001 bei Prof. Dr. Uwe Kastens

Lecture Compiler I WS 2001/2002 / Slide 63

Objectives:

Distinguish cases

In the lecture:

The cases are explained.

Eliminate ambiguities

unite syntactic constructs - distinguish them semantically

Examples:

- Java:
```
ClassOrInterfaceType   ::= ClassType | InterfaceType
InterfaceType          ::= TypeName
ClassType              ::= TypeName

replace first production by
ClassOrInterfaceType   ::= TypeName
semantic analysis distinguishes between class type and interface type
```

- Pascal:
```
factor                 ::= variable | ... | functionDesignator
variable               ::= entireVariable | ...
entireVariable         ::= variableIdentifier
variableIdentifier     ::= identifier                                (**)
functionDesignator     ::= functionIdentifier                         (*)
                       |   functionIdentifer '(' actualParameters ')'
functionIdentifier     ::= identifier

eliminate marked (*) alternative
semantic analysis checks whether (**) is a function identifier
```

Lecture Compiler I WS 2001/2002 / Slide 64

Objectives:

Typical ambiguities

In the lecture:

- Same notation with different meanings;
- ambiguous, if they occur in the same context.
- Conflicting notations may be separated by several levels of productions (Pascal example)

Questions:

Unbounded lookahead

The decision for a **reduction** is determined by a **distinguishing token** that may be **arbitrarily far to the right**:

Example, forward declarations as could have been defined in Pascal:

functionDeclaration ::=
‘function‘ forwardIdent formalParameters ‘:‘ resultType ‘;‘ ‘forward‘

| ‘function‘ functionIdent formalParameters ‘:‘ resultType ‘;‘ block

The distinction between forwardIdent and functionIdent would require to see the forward or the begin token.

Replace forwardIdent and functionIdent by the same nonterminal; distinguish semantically.

Lecture Compiler I WS 2001/2002 / Slide 65

Objectives:

Typical situation

In the lecture:

Explain the problem and the solution using the example

Questions:

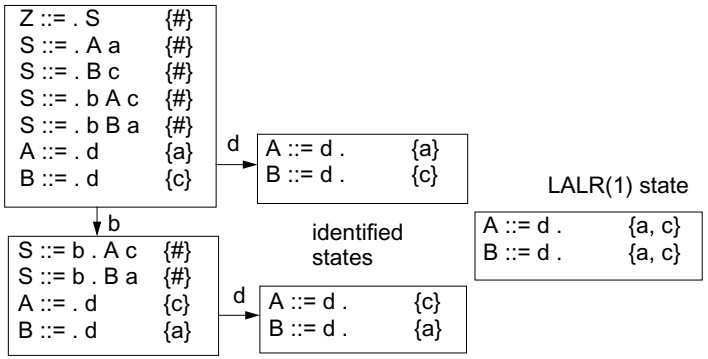
LR(1) but not LALR(1)

Identification of LR(1) states causes non-disjoint right-context sets.

Artificial example:

Grammar:
Z ::= S
S ::= A a
S ::= B c
S ::= b A c
S ::= b B a
A ::= d.
B ::= d.

LR(1) states



Avoid the distinction between A and B - at least in one of the contexts.

Lecture Compiler I WS 2001/2002 / Slide 66

Objectives:

Understand source of conflicts

In the lecture:

Explain grammar the pattern, and why identification of states causes a conflict.
