2. Symbol specifications and lexical analysis

PLaC-2.1

Notations of tokens is specified by regular expressions

Token classes: keywords (for, class), operators and delimiters (+, ==, ;, {), identifiers (getSize, maxint), literals (42, '\n')

Lexical analysis isolates tokens within a stream of characters and encodes them:

Tokens

int count = 0;	double sum = 0.0;	while (count <maxvect)< th=""><th>{</th><th>sum+vect[co</th><th>unt]; count++;}</th></maxvect)<>	{	sum+vect[co	unt]; count++;}

Lexical Analysis

Input: *Program represented by a sequence of characters*

Tasks:

Compiler modul:

Input reader

Recognize and classify tokens Skip irrelevant characters Scanner (central phase, finite state machine)

Encode tokens:

Store token information Conversion Identifier modul Literal modules String storage

Output: Program represented by a sequence of encoded tokens

Avoid context dependent token specifications

PLaC-2.3

Tokens should be **recognized in isolation**:

e. G. all occurrences of the identifier a get the same encoding:
{int a; ... a = 5; ... {float a; ... a = 3.1; ...}}
distinction of the two different variables would require information from semantic analysis

typedef problem in C:

The C syntax requires lexical distinction of type-names and other names:

typedef int *T; T (*B); X (*Y);

cause syntactically different structures: declaration of variable B and call of function x. Requires feedback from semantic analysis to lexical analysis.

Identifiers in PL/1 may coincide with keywords:

```
if if = then then then := else else else := then
Lexical analysis needs feedback from syntactic analysis to distinguish them.
```

Token separation in FORTRAN:

"Deletion or insertion of blanks does not change the meaning."

```
DO24 K = 1,5begin of a loop, 7 tokensDO24 K = 1.5assignment to the variable DO24K, 3 tokensToken separation is determined late.
```

Representation of tokens

Uniform encoding of tokens by triples:

	Syntax code	attribute	source position	
	terminal code of the concrete syntax	value or reference into data module	to locate error messages of later compiler phases	
Examples:		<pre>double sum = 5.6e-5; while (count < maxVect) { sum = sum + vect[count];</pre>		
	DoubleToken Ident Assign FloatNumber Semicolon WhileToken OpenParen Ident	138 16 139	12, 1 12, 8 12, 12 12, 14 12, 20 13, 1 13, 7 13, 8	
	LessOpr Ident CloseParen OpenBracket Ident	139 137 138	13, 14 13, 16 13, 23 14, 1 14, 3	

Regular expressions mapped to syntax diagrams

PLaC-2.6

Construction of deterministic finite state machines

Syntax diagram

set of nodes m_q

sets of nodes m_q and m_r connected with the same character *a*

Construction:

- 1. enumerate nodes; exit of the diagram gets the number 0
- 2. **initial set of nodes** m_1 contains all nodes that are reachable from the begin of the diagram; m_1 represents the **initial state 1**.
- 3. construct new sets of nodes (states) and transitions:
 - chose state q with m_q , chose a character a
 - consider the set of nodes with character a, s.t. their labels k are in m_q .
 - consider all nodes that are directly reachable from those nodes; let m_r be the set of their labels
 - create a state r for m_r and a transition from q to r under a.
- 4. repeat step 3 until no new states or transitions can be created
- 5. a state q is a **final state** iff 0 is in m_q .

deterministic finite state machine

state q

transitions $q \rightarrow r$ with character a

states

PLaC-2.7b

Properties of the transformation

1. **Syntax diagrams** can express languages **more compact** than regular expressions can:

A regular expression for { a, ab, b} needs more than one occurrence of a or b a syntax diagram doesn't.

- 2. The FSM resulting from a transformation of PLaC 2.7a may have more states than necessary.
- 3. There are transformations that **minimize the number of states** of any FSM.

Composition of token automata

Construct one finite state machine for each token. Compose them forming a single FSM:

- Identify the initial states of the single automata and identical structures evolving from there (transitions with the same character and states).
- Keep the final states of single automata distinct, they classify the tokens.
- Add automata for comments and irrelevant characters (white space)

Rule of the longest match

PLaC-2.10

An automaton may contain transitions from final states:

When does the automaton stop?

Rule of the longest match:

- The automaton continues as long as there is a transition with the next character.
- After having stopped it sets back to the most recently passed final state.
- If no final state has been passed an error message is issued.

Consequence: Some kinds of tokens have to be separated explicitly.

Check the concrete grammar for tokens that may occur adjacent!

Scanner: Aspects of implementation

- Runtime is proportional to the number of characters in the program
- Operations per character must be fast otherwise the Scanner dominates compilation time
- Table driven automata are too slow: Loop interprets table, 2-dimensional array access, branches
- Directly programmed automata is faster; transform transitions into control flow:

- Fast loops for sequences of irrelevant blanks.
- Implementation of **character classes**: bit pattern or indexing - avoid slow operations with sets of characters.
- Do not copy characters from input buffer maintain a pointer into the buffer, instead.

Characteristics of Input Data

Identifier module and literal modules

- Uniform interface for all scanner support modules: Input parameters: pointer to token text and its length; Output parameters: syntax code, attribute
- Identifier module encodes identifier occurrences bijective (1:1), and recognizes keywords
 Implementation: hash vector, extensible table, collision lists
- Literal modules for floating point numbers, integral numbers, strings

Variants for representation in memory:

token text; value converted into compiler data; value converted into target data

Caution:

Avoid overflow on conversion!

Cross compiler: compiler representation may differ from target representation

• Character string memory:

stores strings without limits on their lengths, used by the identifier module and the literal modules

Scanner generators

generate the central function of lexical analysis

- GLA University of Colorado, Boulder; component of the Eli system
- Lex Unix standard tool
- Flex Successor of Lex
- **Rex** GMD Karlsruhe

Token specification: regular expressions

- GLA library of precoined specifications; recognizers for some tokens may be programmed
- Lex, Flex, Rex transitions may be made conditional

Interface:

GLAas described in this chapter; cooperates with other Eli componentsLex, Flex, Rexactions may be associated with tokens (statement sequences)
interface to parser generator Yacc

Implementation:

directly programmed automaton in C
table-driven automaton in C
table-driven automaton in C or in Modula-2
faster, smaller implementations than generated by Lex
